1. Box Plots

Comparison of Average Growth Rates in the 1970s: GATT Members vs. Non-Members in Low and Lower Middle Income Countries

The box plots are separated by average GDP per capita and average exports as a percent of GDP of low and low-middle income countries. The data points are separated by year (1970-1979), as well as whether the included countries were a member of the The General Agreement on Tariffs and Trade (GATT). Members are shown in green, and non-members in red. As seen in the box plot, GATT members almost always had a higher GDP per capita, until the latter end of the 1970's. GATT members had overwhelmingly more exports than non-members. These results can be accounted to the GATT's encouragement of free trade, through abolishing protectionist measures in participating countries.

2. Scatter plots

This scatter plot shows the relationship between exports and GDP during the 1970's, separated by region, of low and low-middle income countries. The relationship is mostly linear with some outliers, notably some Middle Eastern/North African countries having a larger GDP per capita than the overall trend.
